Content

- study design
- effects of flow and temperature
- relationship between k_w inside canister to flow outside canister
- mass transfer model for atrazine uptake
- conclusions

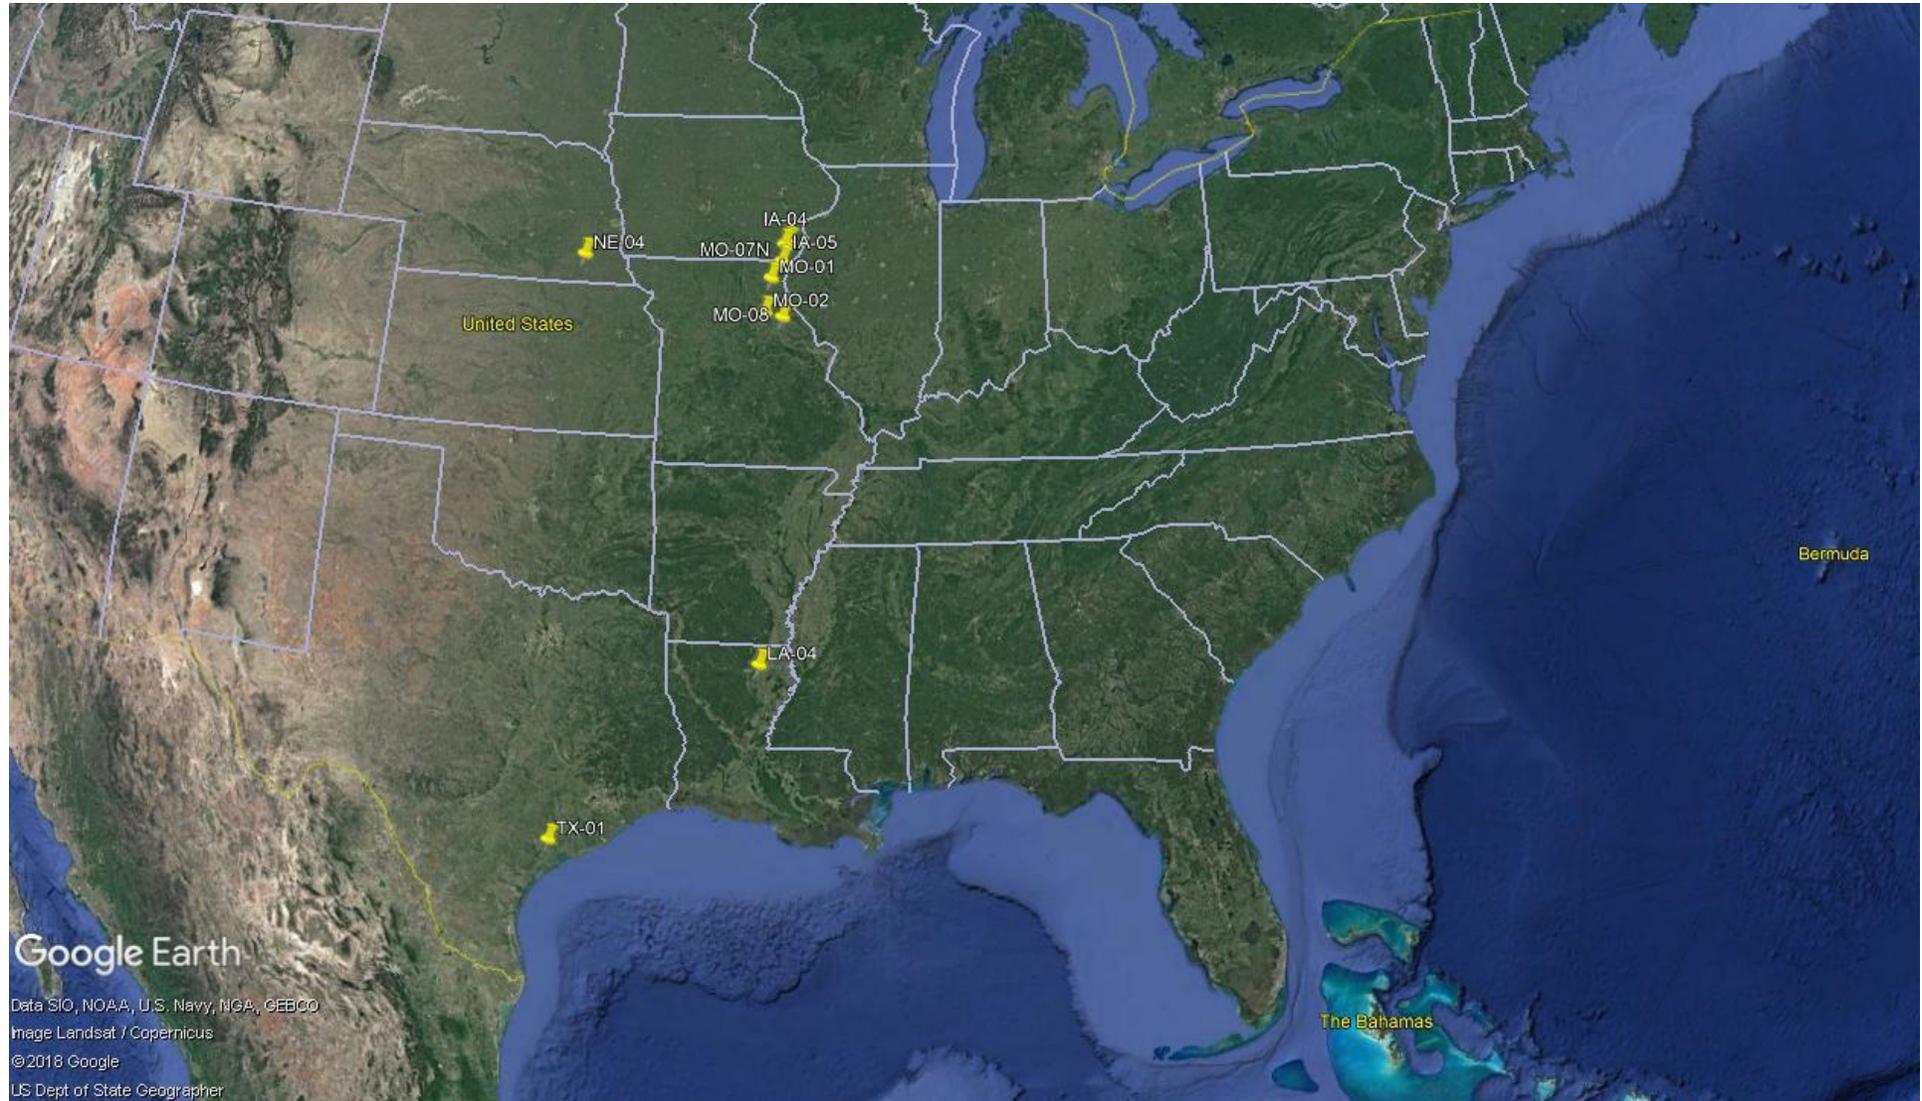

Study Design

- 3 years (2016, 2017, 2018), 9 agricultural sites, 4 to 6 exposure periods of 2 to 3 weeks, 149 sampling rate data
- continuous water sampling with ISCO samplers
- measurement of flow velocities and temperatures
- pictures of sorbent distributions before and after exposure (2018)
- measurement of flow attenuation by POCIS canisters

Study Locations

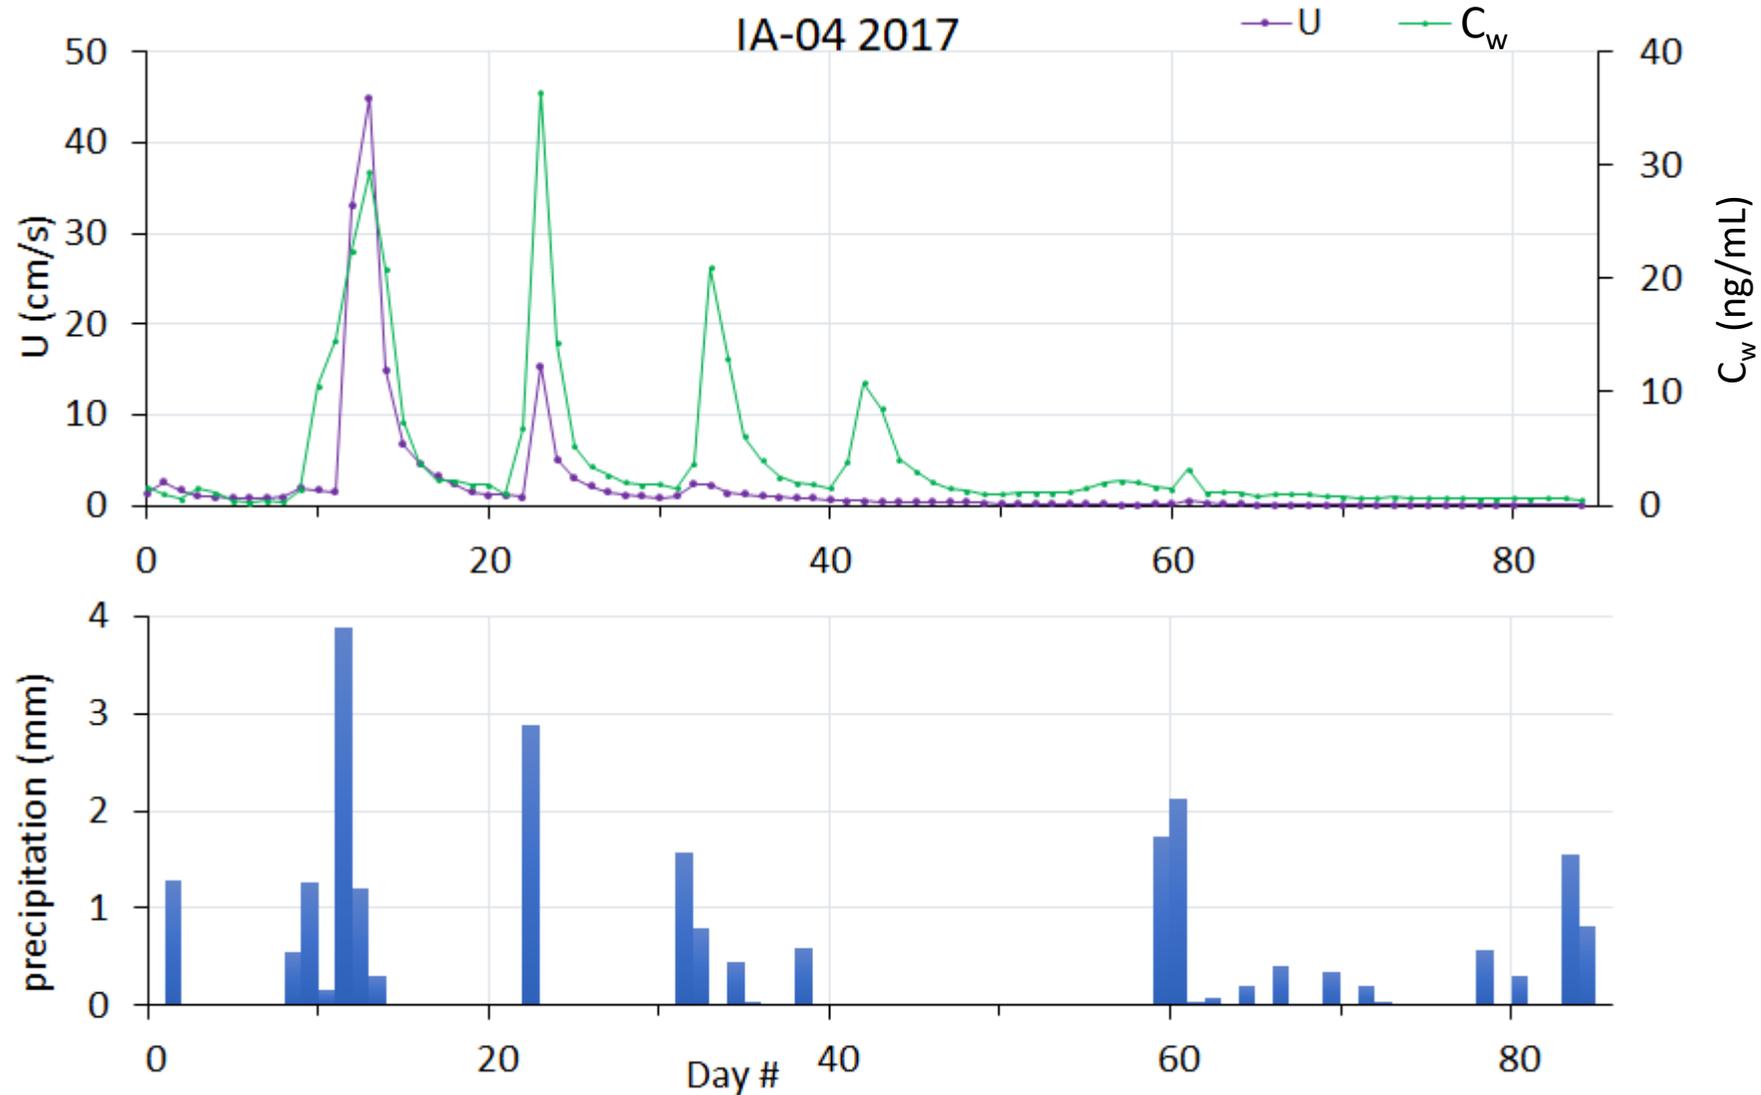

A Representative Monitoring Site

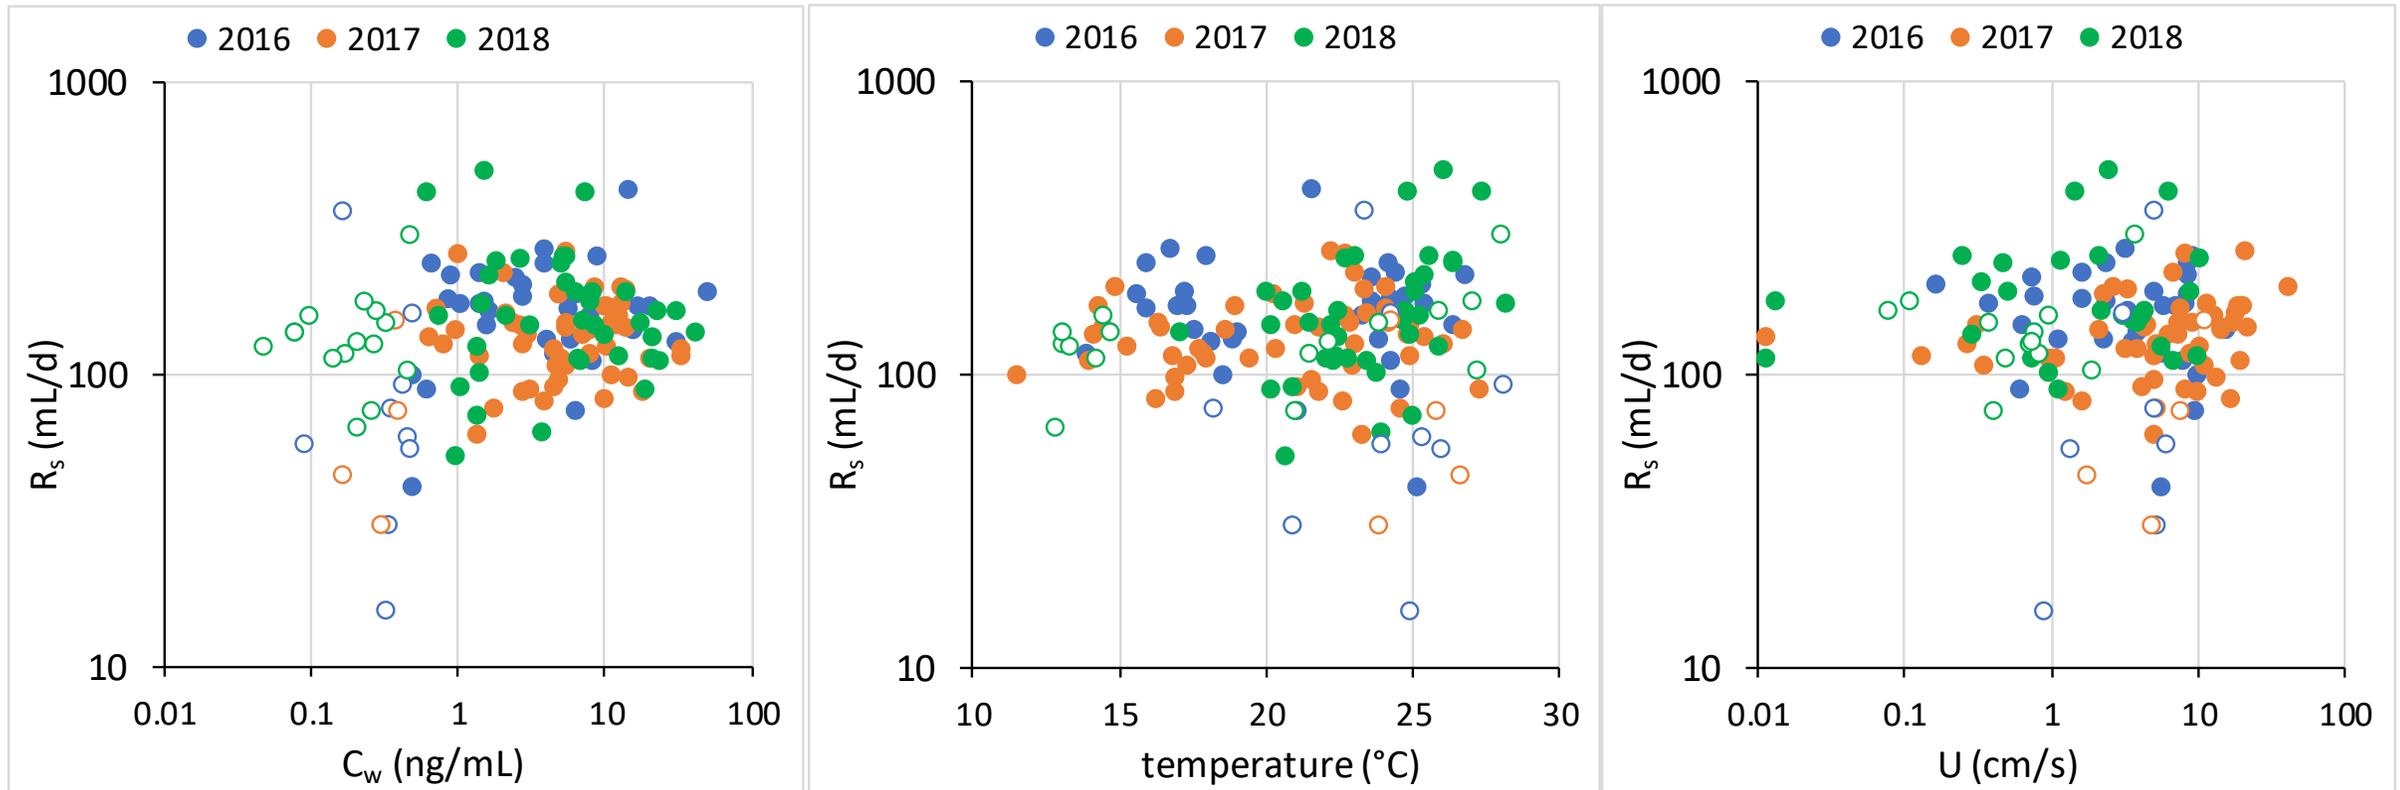

Highly variable concentrations, related to flow and precipitation

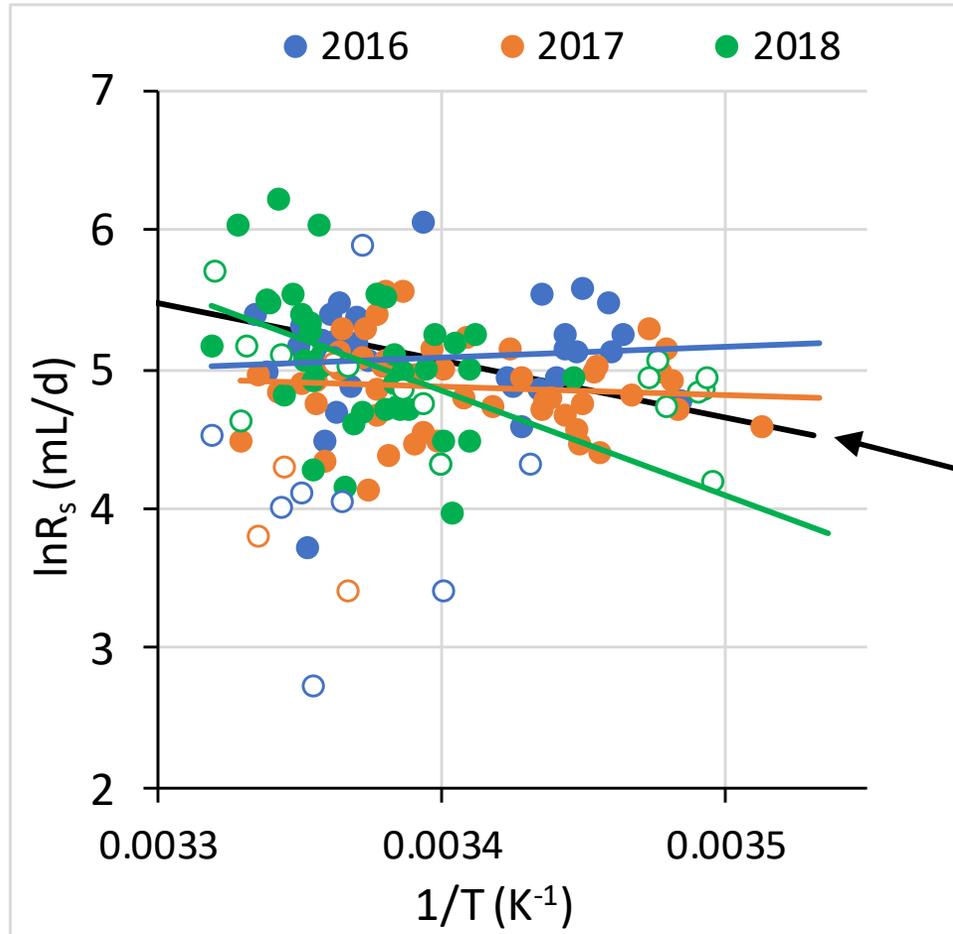

No flow and temperature effects on R_s visible 95% of the R_s between 64 and 334 mL/d

open symbols: $C_w < 0.5$ ng/mL

R_s -Temperature relationship (Arrhenius plot)

Does the canister flatten out flow effects on R_s ?

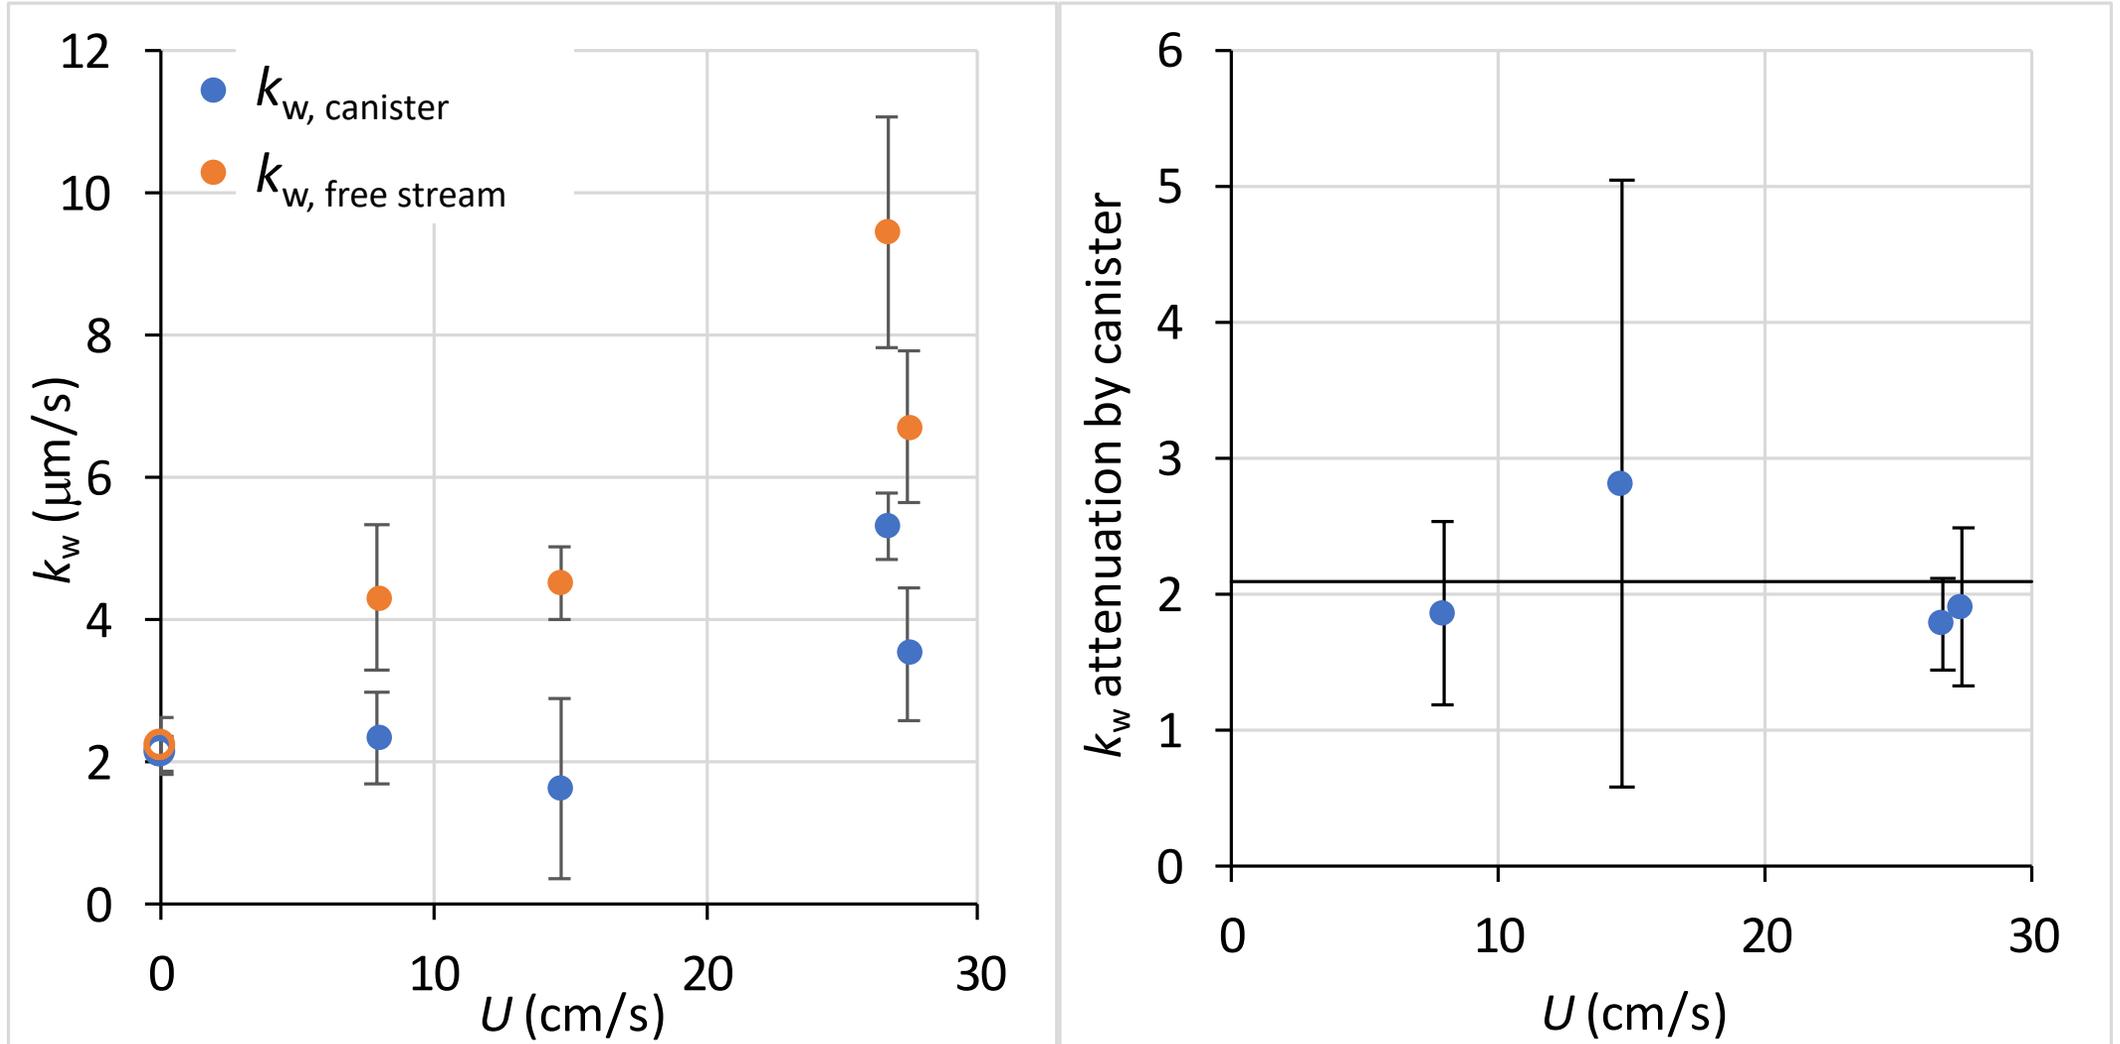

alabaster plate outside canister

alabaster plate inside canister

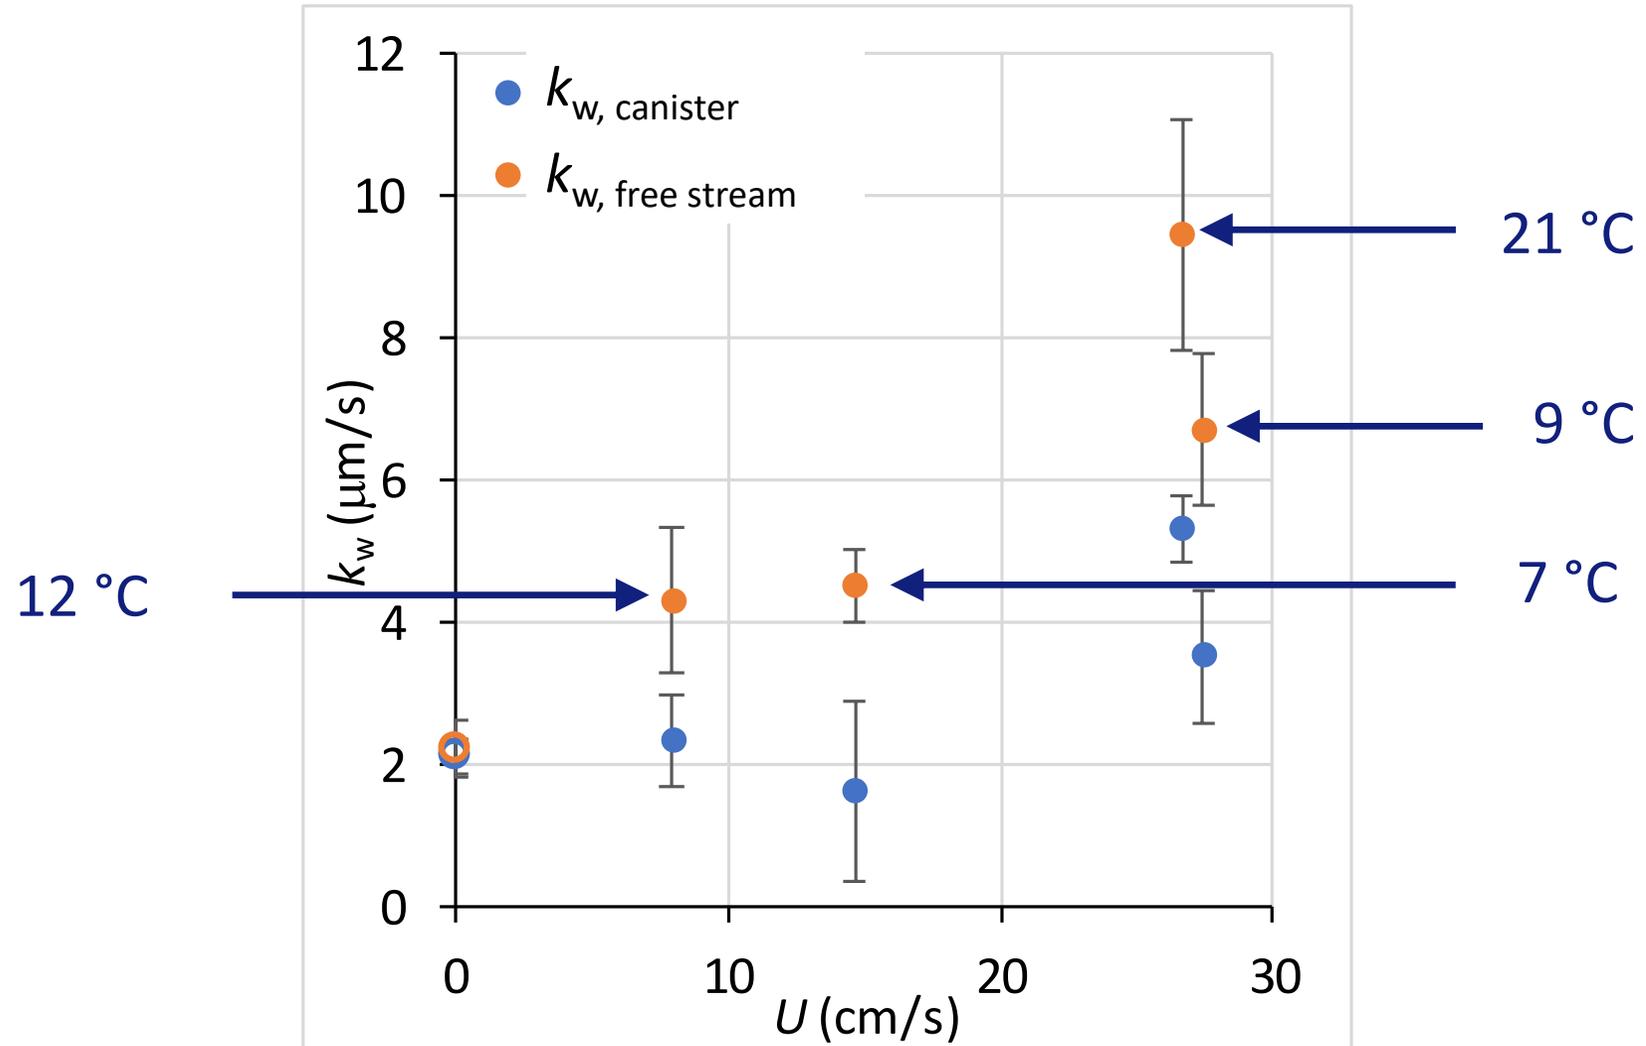

The canister effects on k_w at all U

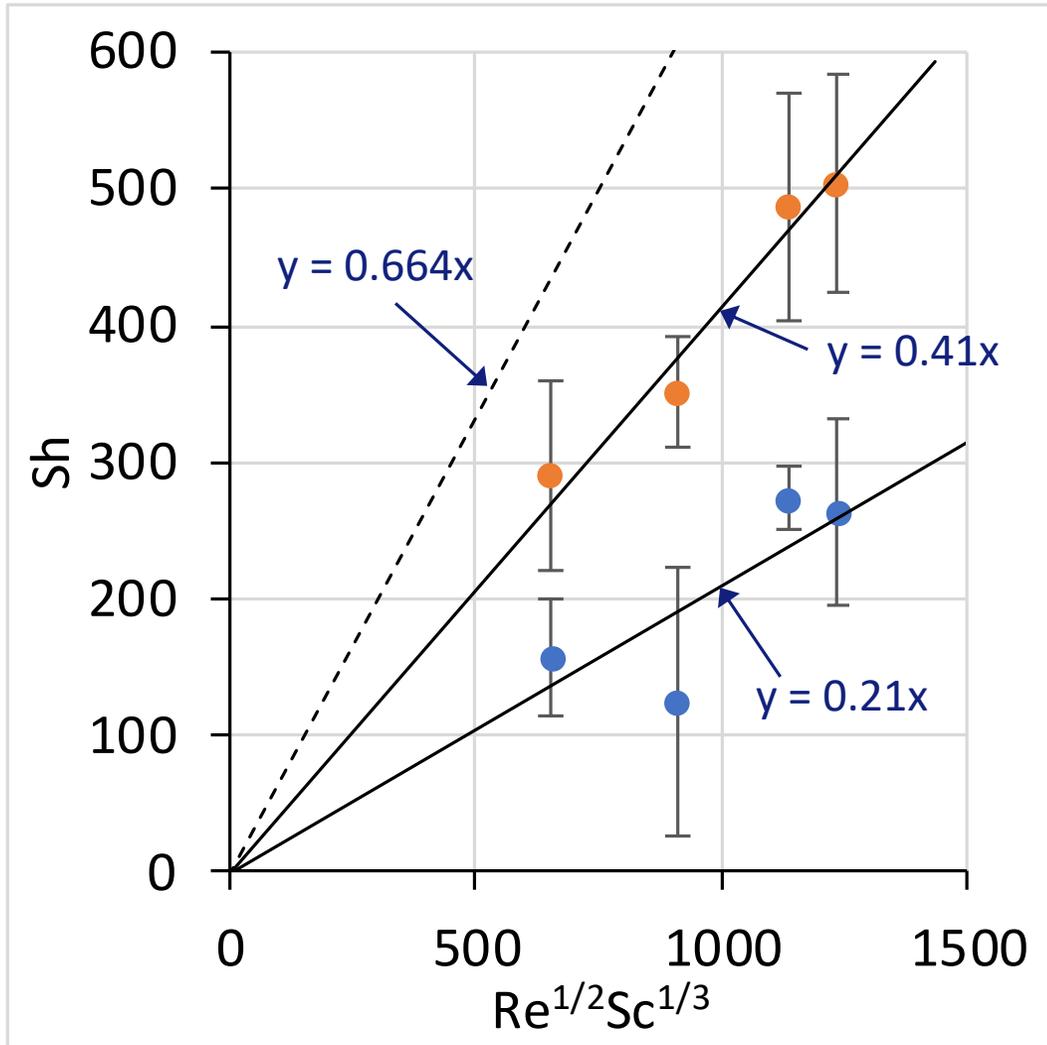

k_w is not a simple function of U

.... but Sh is a simple function of $Re^{1/2}Sc^{1/3}$

k_w inside canister can be linked to U outside canister

$$Sh = \frac{k_w L}{D_w}$$

$$Re = \frac{UL}{\nu}$$

$$Sc = \frac{\nu}{D_w}$$

laminar flow, parallel with flat plate

$$Sh = 0.664 Re^{1/2} Sc^{1/3} \text{ (dashed line)}$$

POCIS outside canister (orange)

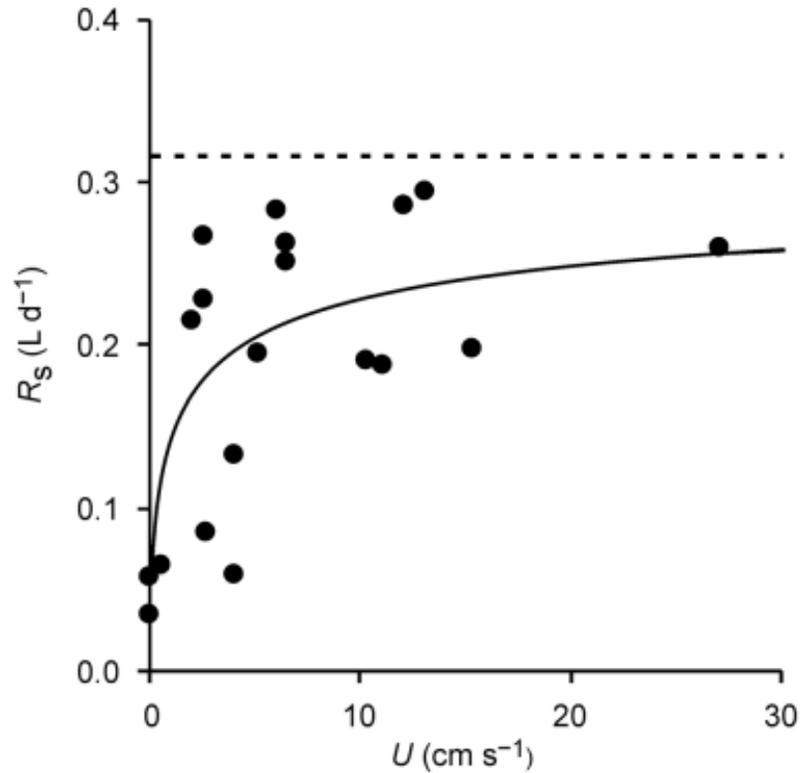

$$Sh = 0.41 Re^{1/2} Sc^{1/3}$$

POCIS inside canister (blue)

$$Sh = 0.21 Re^{1/2} Sc^{1/3}$$

Mixed WBL-membrane control model

literature review data
(Booij & Chen, 2018)

Assume:

- diffusion through pore space only
- sorbent acts as infinite sink

$$\frac{1}{R_s} = \frac{1}{k_w A} + \frac{1}{R_{s,\max}} \quad R_{s,\max} = \frac{\phi D_w}{\tau_w^2 d} A$$

cast in dimensionless form:

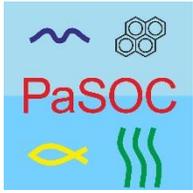

$$\frac{1}{\left(\frac{R_s L}{A D_w} \right)} = \frac{1}{0.21 \text{Re}^{1/2} \text{Sc}^{1/3}} + \frac{1}{\left(\frac{\phi L}{\tau_w^2 d} \right)}$$

\uparrow Overall \uparrow WBL \uparrow membrane

$$\text{Sh} = \frac{k_w L}{D_w}$$

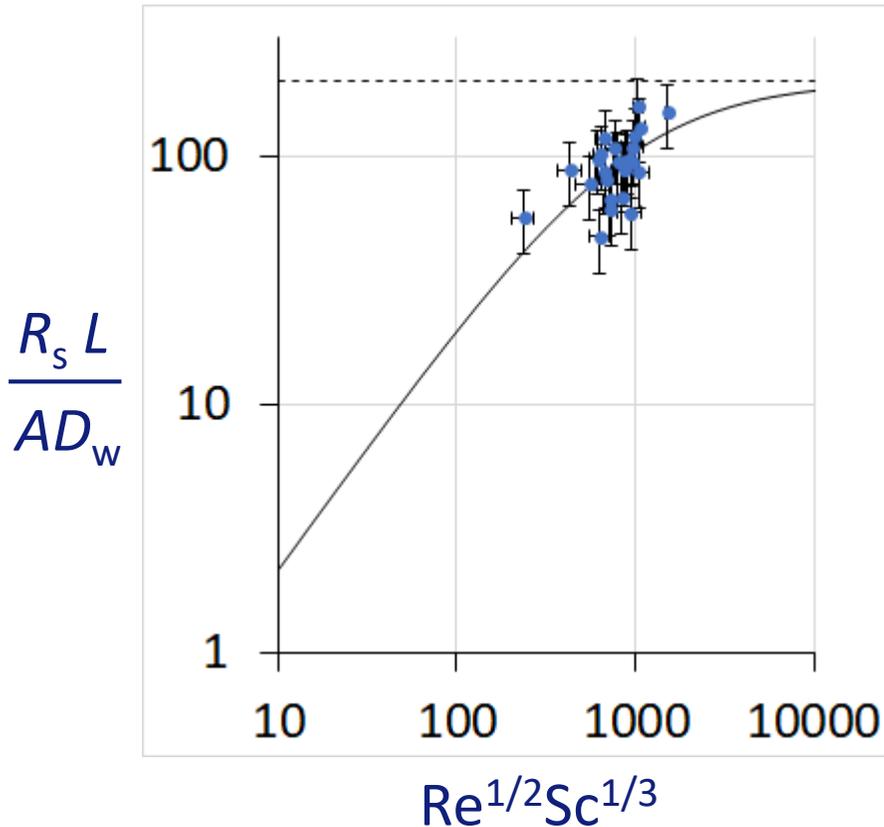

$$\text{Re} = \frac{UL}{\nu}$$

$$\text{Sc} = \frac{\nu}{D_w}$$

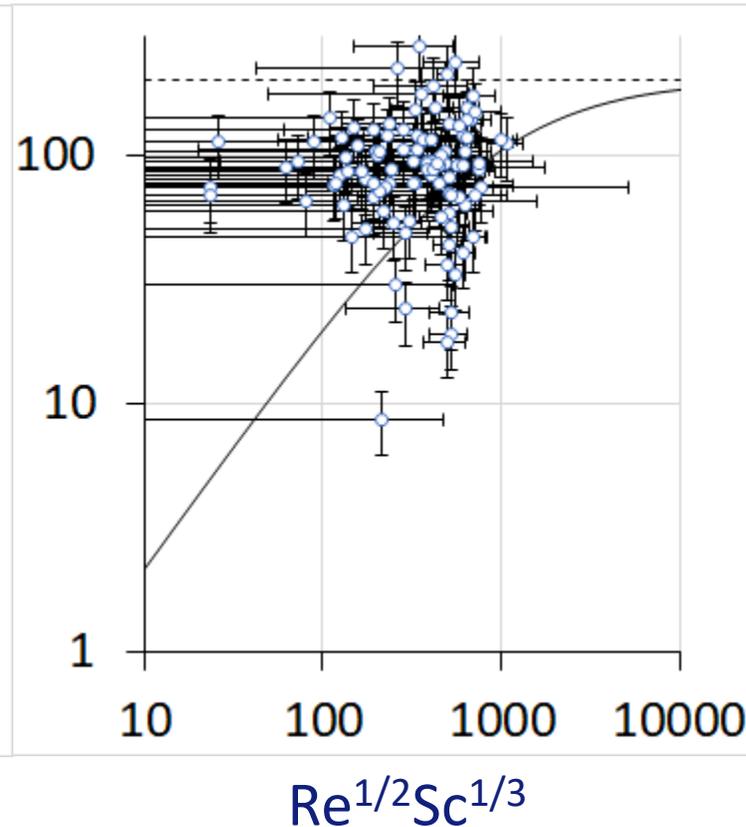

Model could only be tested for a small (17%) part of the data due to large uncertainty in U

U values with small uncertainty

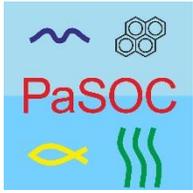

U values with large uncertainty

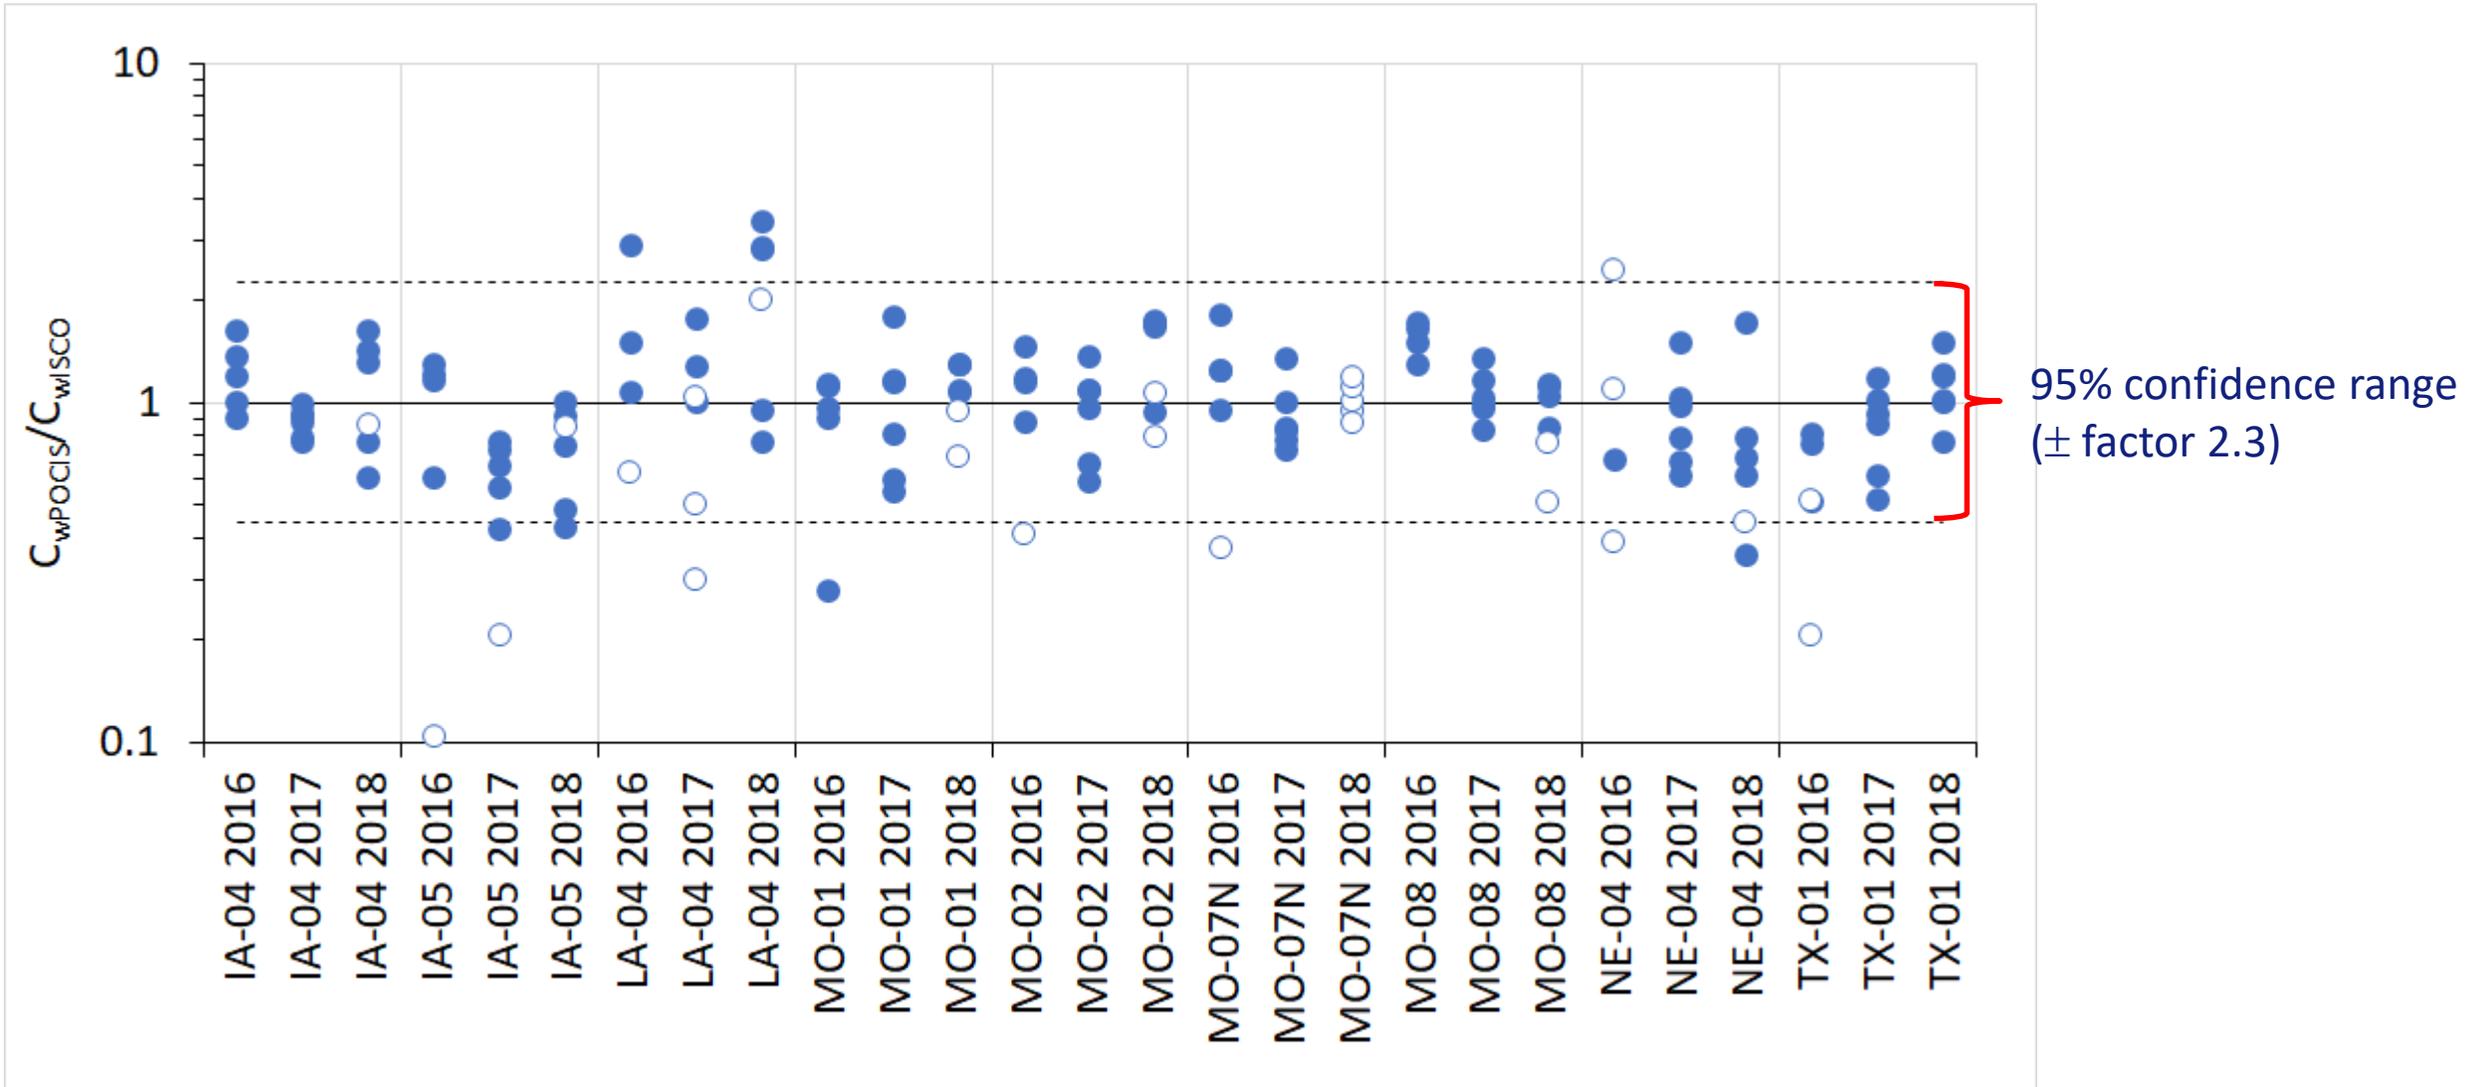

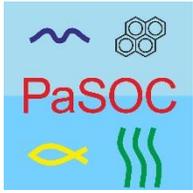

$$\left(\frac{R_s L}{A D_w} \right) = \frac{1}{0.21 \text{Re}^{1/2} \text{Sc}^{1/3}} + \left(\frac{\phi L}{\tau_w^2 d} \right)$$

Exchange surface area
11 cm²
Exposed membrane area
46 cm²

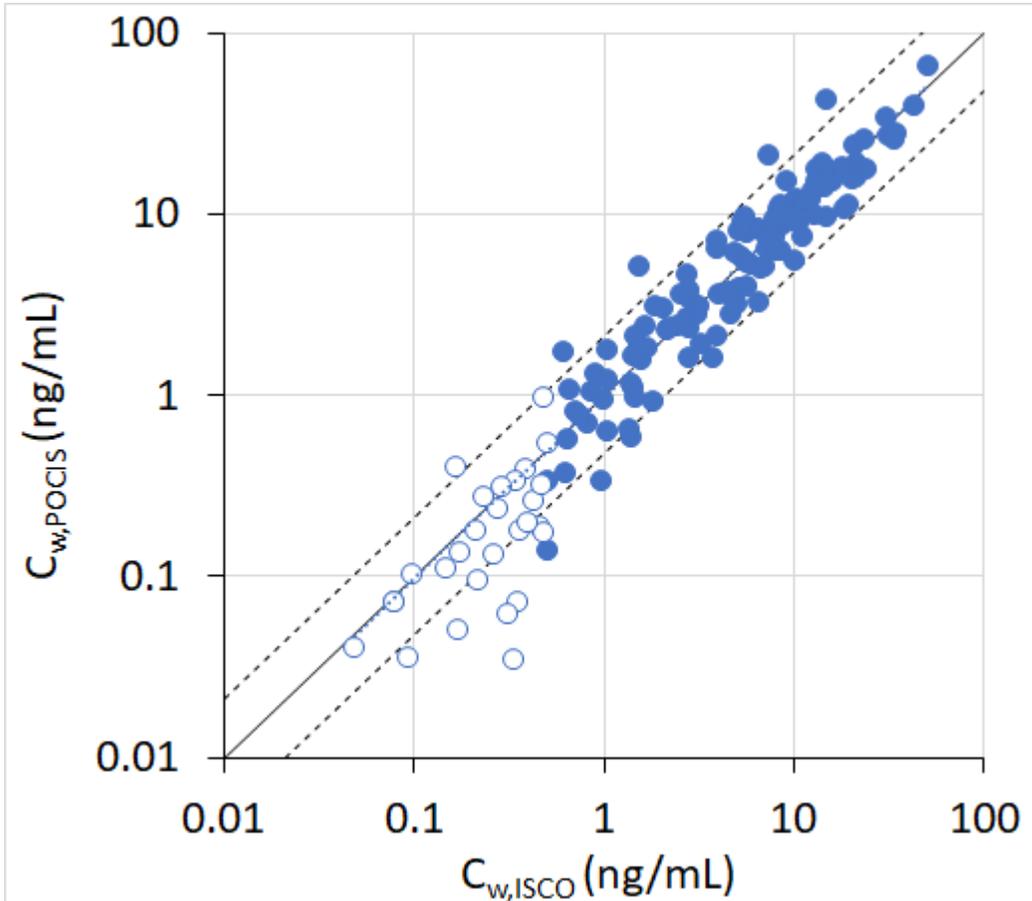

So far, $R_s = 147$ mL/d is the best available model applicable to all sites and years

1:1 correspondence of $C_{w,POCIS}$ and $C_{w,ISCO}$

Drawn line = 1:1 relationship

Dashed lines span the 95% confidence range

Open symbols: $C_{w,ISCO} < 0.5$ ng/mL

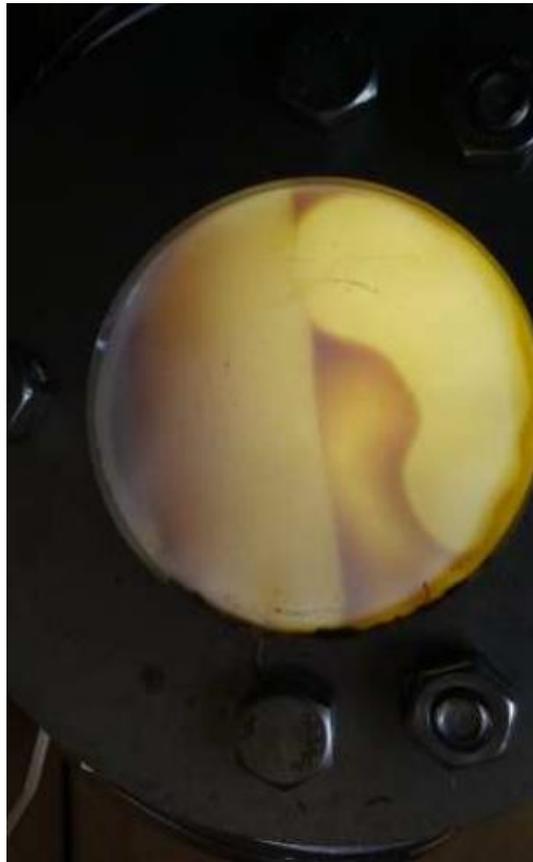

Exchange surface area is time variable (Sorbent moving around in the membrane envelope)

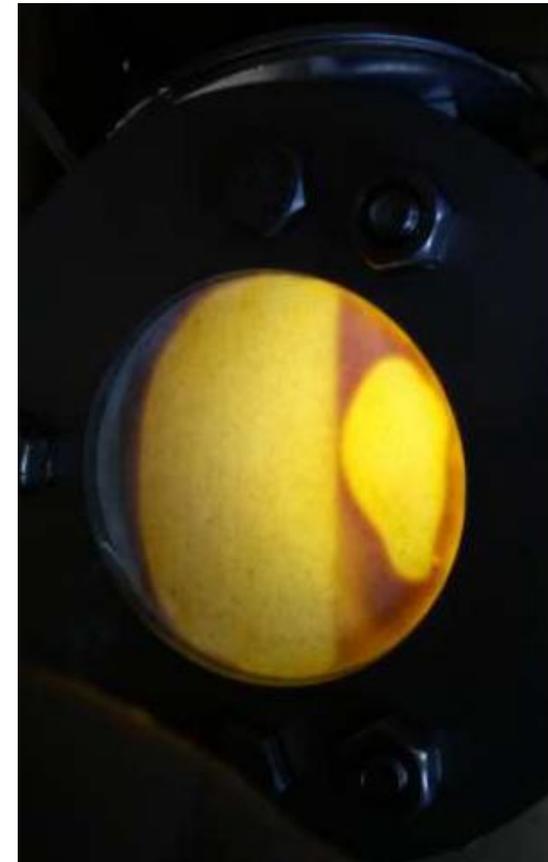

before deployment

at mid-term check

after deployment

Conclusions

- Presently best available method for modeling atrazine sampling rates is to adopt a temperature and flow independent sampling rate of 147 mL/d.
- POCIS based concentrations showed a 1:1 relationship with ISCO with a precision factor of 1.5 (standard deviation) or 2.3 (95% confidence level).
- Flow effects are not reduced by the POCIS canisters
- An engineering approach in modeling could be useful (dimensionless numbers)
- Variability of factor 1.5 may be related to
 - sorbent coverage of the membrane
 - fouling (the usual suspect)
- POCIS offers potential as an alternative to conventional sampling method
